

Array

1	5	17	3	25
---	---	----	---	----

Definition

Array:

Contiguous area of memory

Definition

Array:

Contiguous area of memory consisting of equal-size elements indexed by contiguous integers.

What's Special About Arrays?

What's Special About Arrays?

Constant-time access

What's Special About Arrays?

Constant-time access

array_addr

What's Special About Arrays?

Constant-time access

$\text{array_addr} + \text{elem_size} \times (\quad)$

What's Special About Arrays?

Constant-time access

$\text{array_addr} + \text{elem_size} \times (i - \text{first_index})$

Question

Given an array whose:

- address is 1000,
- element size is 8
- first index is 0

What is the address of the element at index 6?

40

48

1048

1040

1006

1005

HW

- 1. What is the time complexity of removing an element from the end of an array and why?**
- 2. Consider the array [8, 3, 12]. What is the time complexity of adding the number 5 at the second position, and why?**
- 3. If you want to remove the first element in the array [8, 3, 12], what would be the time complexity and the reason for this complexity?**
- 4. What would be the time complexity of inserting an element at the third position of the array [8, 3, 12] if the array is not full?**

HW

4. Given the pseudocode below, what is the time complexity of adding a new element at the beginning of an array, and why?

```
function addAtBeginning(array, new_element)
  for i from length(array) to 1 do
    array[i] = array[i-1]  // Shift all elements to the right
  end for
  array[0] = new_element  // Insert new element at index 0
end function
```

HW

5. Examine the pseudocode below. What is the time complexity of removing an element from the end of an array and why?

```
function removeAtEnd(array)
  last_element = array[length(array) - 1] // Access the last element
  array[length(array) - 1] = null        // Remove the last element
  return last_element
end function
```

HW

6. In the provided pseudocode, how is the 5th element of the array accessed in constant time ($O(1)$) using the formula $\text{array_addr} + \text{elem_size} \times (\text{index} - \text{first_index})$?

```
function accessElement(array_addr, elem_size, index, first_index)
    offset = elem_size * (index - first_index)
    element_address = array_addr + offset
    return element_at(element_address)
end function
```

```
array_addr = 1000    // Base address of the array
elem_size = 4        // Each element is 4 bytes
index = 5            // Access the 5th element
first_index = 0      // Arrays are 0-indexed
```

```
element = accessElement(array_addr, elem_size, index, first_index)
```
